

## Dependable Systems

### 4. Chapter Impairments

Prof. Matthias Werner  
Operating Systems Group

## 4.1 Technical Terms

Failure / Fault / Error

- ▶ In general: Behavior differs from specification or expectation
- ▶ **Impairment**: Holistic view, considers also load, weaknesses etc. .

### Definitions by LAPRIE

- ▶ **Failure**: Occurs when the delivered service deviates from the specified service. Failures are caused by errors
- ▶ **Error**: Derivation of the system's state from expected state (program or data); deviation from the expected result of computation (incorrect result) .
- ▶ **Fault**: Adjudged or hypothesized cause of an error

\* Beachten Sie bitte, dass in der deutschen (Umgangs-)Sprache alle Konzepte mit "Fehler" bezeichnet werden.

## Characterization of Faults

High diversity in possible sources and types

- ▶ **Fault nature:**
  - ▶ **Accidental** faults vs. **intentional** faults
- ▶ **Fault origin viewpoints**
  - ▶ Phenomenological causes: **physical** faults vs. **human-made** faults
  - ▶ System boundaries: **internal** faults vs. **external** faults
  - ▶ Phase of creation: **design** faults vs. **operational** faults
- ▶ **Temporal persistence:**
  - ▶ **Permanent** faults vs. **temporary** faults

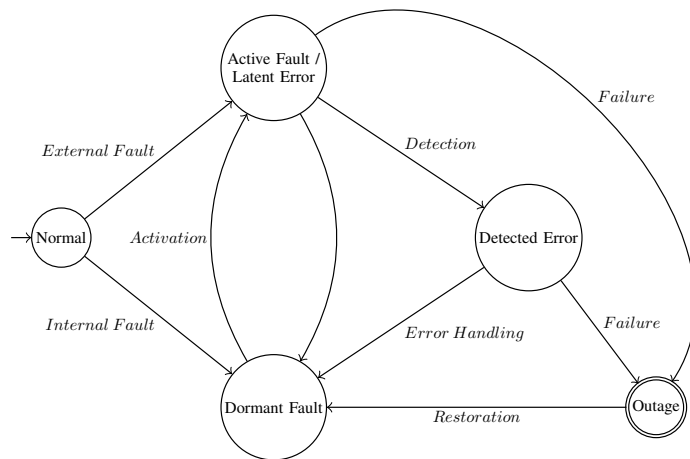

## Temporal Characterization

- ▶ A fault is **active** when it produces an error
- ▶ A non-active internal fault is a **dormant** fault
  - ➔ often cycling between dormant and active
- ▶ Temporary external accidental physical faults are also called **transient faults**
- ▶ Temporary internal accidental faults are also called **intermittent faults**
- ▶ **Examples:**
  - ▶ Pattern-sensitive memory hardware, system overload
  - ▶ Arbitrary concept-dependent faults with unknown activation condition

## Fault Automaton

- The temporal relations can be described by a **fault automaton**

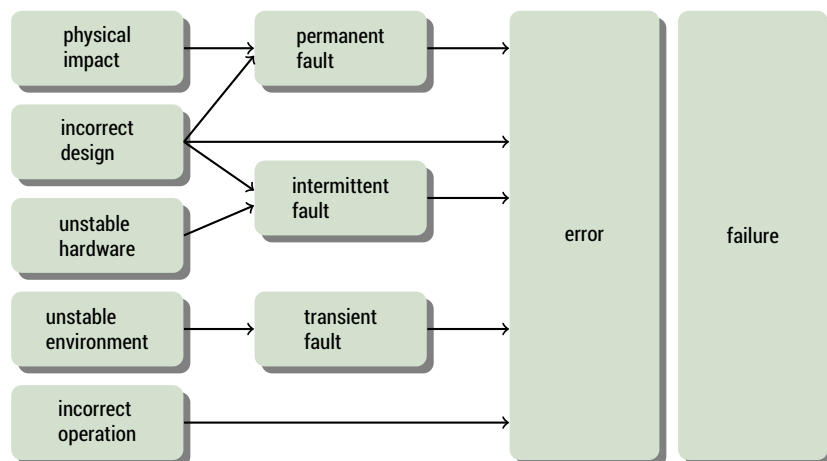

## Discussion

- An external fault is a design fault – inability or refusal to foresee all situations
  - **Example:** performance or timing faults (derivation from expected load / timing)
- Design faults are created during system development, system modification, or operational procedure creation and establishment
- Physical faults are **accidental faults**
- Intentional and design faults are human-made faults
- Many specialized versions of the term “fault”, e.g. **bug**
  - **Heisenbug** – Intermittent software fault
  - **Bohrbug** – Permanent software fault
  - **Mandelbugs** – Appear chaotic due to many dependencies

## Sources of Error

(Siewiorek/Swarz)

## Errors

- State of the system, not an event
- Escalates to failure depending on
  - Intentional / unintentional redundancy
  - System activity
  - User's definition of a failure
- **Examples:** maximum outage time, acceptable delay, retransmission rate
- Latent (not recognized) vs. detected error coming from an active fault

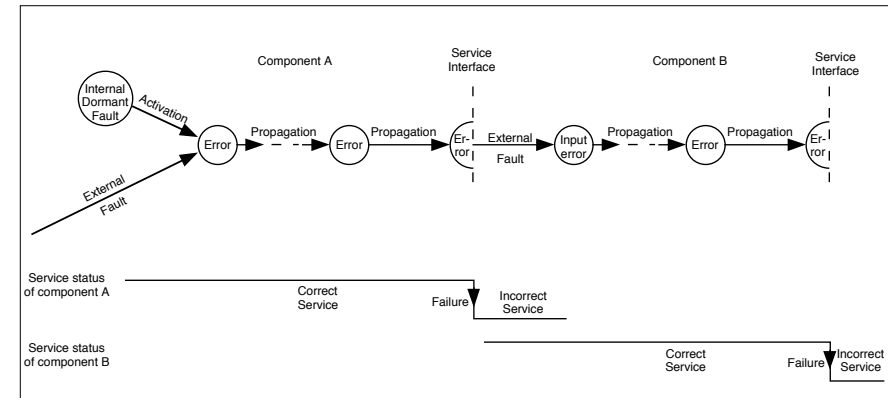

## Error Messages (HANSEN & SIEWIOREK)

- ▶ Same fault can lead to different errors
- ▶ Detected errors might not be logged

## Propagation

- ▶ **Source:** Algirdas Avizienis et al. "Basic Concepts and Taxonomy of Dependable and Secure Computing". In: *IEEE Transactions on Dependable and Secure Computing* 1.1 (2004), pp. 1–23

## Fault Failure Model

### Alternative view: KOPETZ

No states are considered, but events only

- ▶ **fault:** undesired event
- ▶ **failure:** event of derivation in function; may constitute *fault* in the next level of abstraction

## 4.2 Impairment Models

### System and Fault Model

- ▶ **Fault tolerant system design:** Seems to be a contradiction in terms:
  - ▶ Design requires specification (what to expect?)
  - ▶ Faults are deviations from specification
- ▶ **Solution:** Specification for fault free case + additional fault
- ▶ **Caution:** Interdependencies between system model and fault specification ➡ **fault model**

## Coverage

### Coverage

**Coverage** of a fault model is the ratio of the number of faults that can be described by the model to the number of faults that occur in reality.

- ▶ Used to evaluate a test's performance
- ▶ Tests are always based (at least **implicitly**) on a specific fault model
- ▶ Usually one fault model is evaluated against another that covers more faults
- ▶ The actual coverage can only be derived empirically

## Fault Models

Fault models can be described at different levels of abstractions:

- ▶ (Physics (unusual))
- ▶ Circuit level
- ▶ **Switching [circuit] level**
- ▶ Register transfer level
- ▶ PMS-level (processor-memory-switch)
- ▶ **System level**

## Fault Models at Switching Level

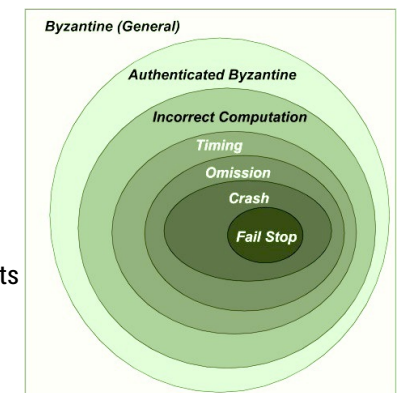

- ▶ Fault models at switching level are mainly used in two areas:
  - ▶ Design of circuits (for us not very interesting)
  - ▶ Communication
- ▶ Logical faults at wires are considered:
  - ▶ **Stuck-at- $X$  faults**: Signal is always  $X$  ( $X \in \{0, 1, valid, \dots\}$ )
  - ▶ **Bridging faults** (short circuits)
  - ▶ **Stuck-at-open faults** (undefined signal)

## Fault Models for Distributed Systems

- ▶ Crash fault
- ▶ Omission fault
- ▶ Timing fault
- ▶ Incorrect computation/communication
- ▶ Arbitrary/ byzantine fault<sup>†</sup>

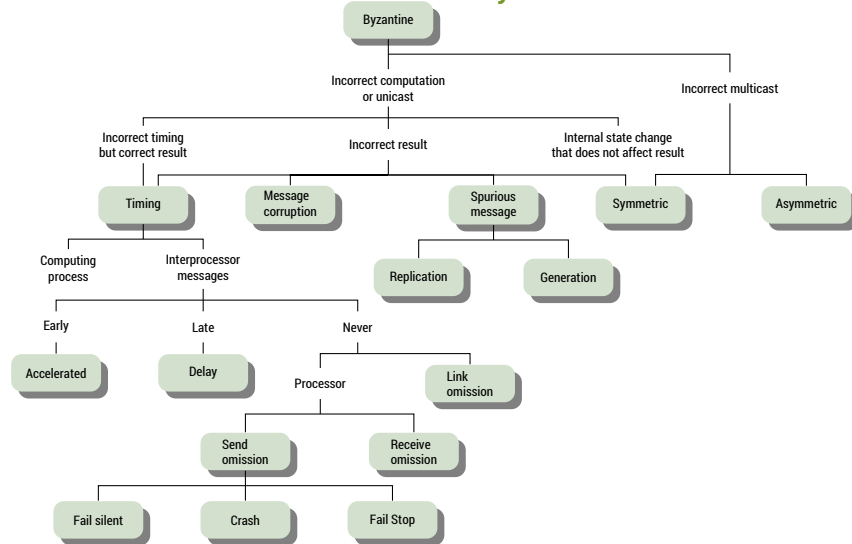

Link faults are mapped onto component faults of the sender or receiver

<sup>†</sup>In case of authenticated Byzantine faults, one assumes that no message can be inwardly altered.

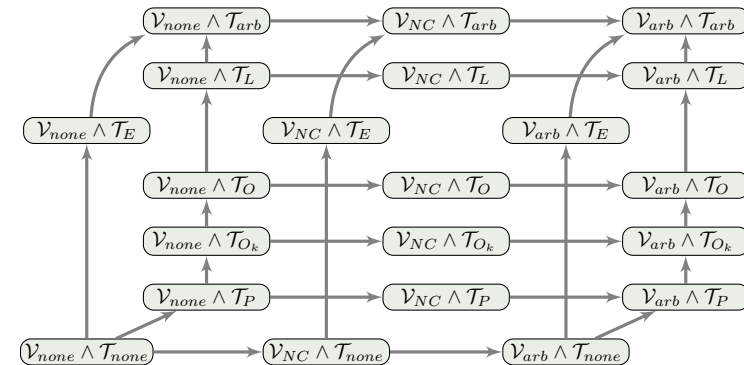

## Fault Hierarchies in Distributed Systems

## Partial Order of System Faults

- Arrows represent decreasing strictness of assumptions
- $\mathcal{V}$ : value domain,  $\mathcal{T}$ : time domain

$P$  – permanent;  $O_k$  – sequential omission;  $O$  – omission;  $L$  – belate;  $E$  – premature;  $NC$  – coding;  $arb$  – arbitrary

## Statistical Assumptions

- Usually it is not sufficient to know the **impact** of faults
- Statements regarding **occurrence** are necessary
  - How many faults at the same time (maximum)?
  - How often?
  - Independence of faults
- **Independence** of faults
  - Are faults occurring independent from each other?
  - Are faults correlated?
  - Are faults intended (attack)?

## Statistical Assumptions (cont.)

- Statistical assumption usually consider mean values
  - Mean time to failure (MTTF, cf. Chapter 2):

### Mean time to failure

$f(t)$  is the density of the probability that **no failure** occurs until time  $t_0 + t$ .

$$\bar{t}_F = \int_0^{\infty} t \cdot f(t) dt$$

- For failures with exponential distribution:  $\bar{t} = MTTF = \frac{1}{\lambda}$

## Faults as Stochastic Process

- ▶ Arrival of faults (or load/requests) is often described as **stochastic process**
- ▶ **Recap:**

### Definition 4.1 (Stochastic process)

A **stochastic (or random) process** is a set  $\{X(t)\}$  of random variables with a shared value domain (state space) and a shared index parameter  $t$ .

- ▶ Each instance of index  $X(t)$  is a random variable for fixed  $t$
- ▶ Usually,  $t$  is interpreted as time (especially for arrival processes)

## Poisson Process

- ▶ Counting events of a discrete process until  $t_0 + t$
- ▶ Number is  $N(t)$
- ▶ It holds:
  - ▶  $N(t_0) = 0$
  - ▶ Independence in not overlapping intervals
  - ▶ Probability of an event only depends on  $t$ , not on  $t_0$
  - ▶  $\lim_{t \rightarrow 0} \Pr\{\text{event in } t\} \sim t$

Then this is called a **Poisson-Prozess** and for  $N(t)$  holds:

$$\Pr\{N(t) = m\} = \frac{(a \cdot t)^m}{m!} e^{-a \cdot t}$$

## Poisson Process (cont.)

- ▶  $N(t)$  represents numbers of faults in interval
- ▶ Special case: Time to the **first** fault

$$\begin{aligned} \Pr\{N(t) = m = 0\} &= \frac{(a \cdot t)^m}{m!} e^{-a \cdot t} \\ &= \frac{(a \cdot t)^0}{0!} e^{-a \cdot t} \\ &= e^{-a \cdot t} \end{aligned}$$

- ➔ equals known probability of survival for constant fault rate (exponential)
- ➔ More in Chapter 7

## Discussion: Fault and Load

### Interaction between load and classical failures

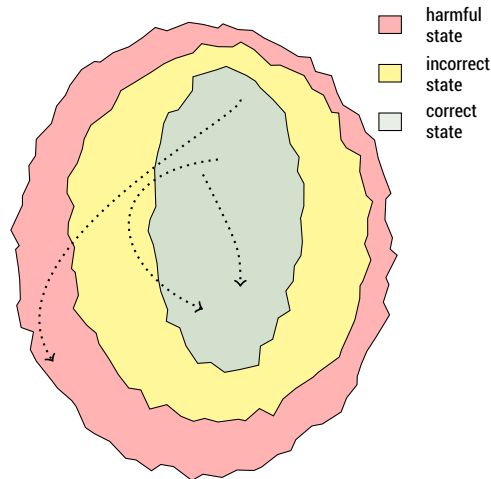

- ▶ Usually positive correlated:
  - ▶ Increasing load leads to **wearout**
    - ➔ Failure rate increases
  - ▶ Higher load shows cause of failure faster
    - ➔  $\Pr\{\text{error|fault}\}$  increases
  - ▶ (Recognized) faults lead to recovery measures
    - ➔ Load increases
- ▶ Feedback possible
- ▶ Sometimes load **decreases** failure rate

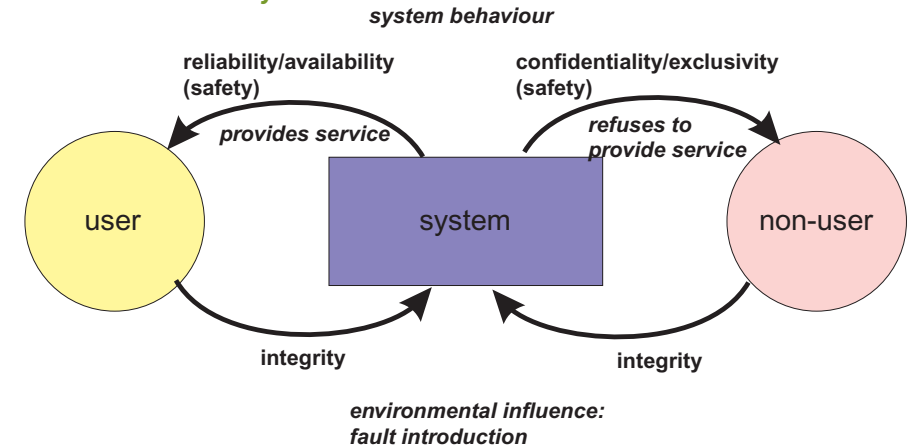

## 4.3 Alternative Descriptions

### Description of Behavior

- Considers computer as automaton
- States may include time
- Sequence of states describes correct or incorrect behavior

## Holistic Model by JONSSON

- Attempt of standardization
- Includes security

## Multiple Causes (D. ORLANDELLA and J. REASON)

- Sometimes it is not possible to detect **the** root cause but the concurrence of several causes
- Description of potential impairments
- Swiss-Cheese-Model
